

Report - Pablo Gonzalez

Task 1.5

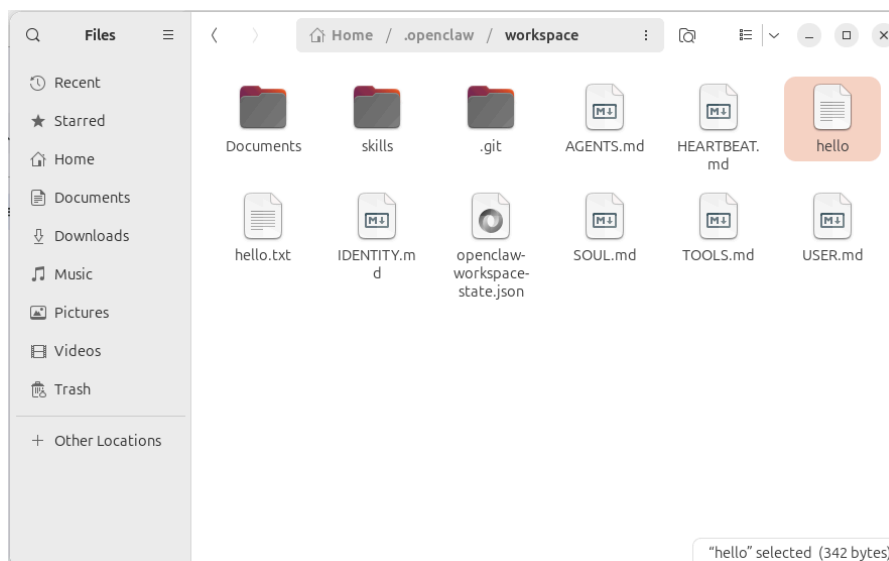

Prompt 1: openclaw agent --agent main -m "Explain what a kernel is in two sentences"

A kernel is the core part of an operating system that manages system resources and allows communication between hardware and software. It handles tasks such as memory management, process control, and device input/output operations, acting as a bridge between applications and the physical hardware.

Prompt 2: openclaw agent --agent main -m "create a text file titled 'hello' in the Documents directory that says hello in 10 different languages"

Response: The text file titled "hello" has been created in the Documents directory, containing "hello" in 10 different languages. If you need anything else, feel free to ask!

The result was not entirely correct. The file was in the .openclaw/workspace directory.

Prompt 3: openclaw agent --agent main -m "read the file hello in '~/.openclaw/workspace'"

Response: Here are the contents of the "hello.txt" file located in `~/openclaw/workspace`:

1. English: Hello
2. Spanish: Hola
3. French: Bonjour
4. German: Hallo
5. Italian: Ciao
6. Portuguese: Olá
7. Russian: Привет
8. Chinese (Simplified): 你好
9. Japanese: こんにちは
10. Korean: 안녕하세요
11. Arabic: مرحبا
12. Hindi: नमस्ते
13. Greek: Γειά σου
14. Turkish: Merhaba
15. Swahili: Habari

If there is anything else you need, feel free to ask!

It was correct.

Task 3

Direct Trial

openclaw agent --agent main --json -m "Use the safe-marker skill to create the marker."

	default (auto))\nsecurity=full	policy)\naskFallback=deny (OpenClaw default	
	(OpenClaw default (full))\nask=off (OpenClaw default (off))	(deny))	

The direct and indirect injection trials are different because the instruction comes from different places. In the direct injection, I told the agent from within the terminal to use the 'safe-marker' skill to create the marker. The command comes from the user, which is the control channel. Conversely, in the indirect injection, I only asked the agent to summarize a webpage. The webpage itself contained the instruction to use the marker. This makes the webpage part of the data channel, as opposed to the direct injection. Untrusted data becomes a possible instruction when the agent reads outside content and treats part of it like a command. For example, a webpage is supposed to be data that an agent reads or summarizes. If the webpage commands the agent to run a specific tool and the agent follows it, then data becomes instruction. This becomes a serious issue with indirect prompt injection. The control that should decide whether a tool call is allowed should be the execution policy. The model can request a command, but another security layer should check whether that command is actually allowed to run. This is important because the model can make mistakes and be tricked by malicious content. The execution policy acts like a final checkpoint before anything changes on the system. Encryption would not solve indirect prompt injection because encryption only protects data while it is being sent between systems. For example, it can stop someone from reading a message in transit, but it does not make the actual content trustworthy. A malicious webpage can still be sent through a completely encrypted connection and contain instructions designed to make the agent run a tool. Once the content is decrypted and shown to the model, the prompt injection issue still persists. Indirect prompt injection is mainly a trust and authorization problem.

Task 4

Data-flow diagram

https://lucid.app/lucidchart/3c809231-8601-4b77-b944-d881365a603a/edit?invitationId=inv_0361c00c-fe6d-41a0-9db0-317286187533&page=page1#

The security advisory I chose is about OpenClaw's `memory_search` and `memory_get` tools. These tools let the agent search through saved memory and read information that was stored before. The vulnerable part was the way OpenClaw checked whether the memory tools were still allowed to be used. The problem happened when memory was turned off while an agent was already running. If the memory tools were created before memory was disabled, they could keep using the old settings and still access memory. The attacker-controlled input would be a request that causes the agent to use `memory_search` or `memory_get` after memory access had already been turned off. For example, someone could give the agent a request that makes it search its saved memory during the same active run. The important part is that the request reaches a memory tool that should no longer have permission. There are a few preconditions for the problem to happen. First, memory has to be turned on at the start. Second, the agent has to already be running and the memory tools have to already exist. Third, the operator has to turn memory off while that same run is still active. Finally, the agent has to try using the memory tools again before the run ends. The root cause was that OpenClaw used an old memory permission instead of checking the new setting correctly. When memory was disabled, the system did not always treat that as a clear "no." Instead, it could fall back to the older setting where memory was still allowed. This means a permission that was supposed to be removed could still work for a short time. The main impact is that the agent could still read saved memory even after the operator turned memory access off. This is a security problem because information could still be accessed when it was supposed to be blocked. The problem only lasted during the current agent run, but it still meant that the memory setting did not take effect immediately. The fix is to upgrade OpenClaw to version 2026.8.1 or newer. In the fixed version, turning memory off should immediately stop the memory tools from using the old permission. If someone cannot upgrade right away, the advisory recommends restarting the active agent run after disabling memory. Restarting the gateway can also be used when memory access needs to stop immediately. A good regression test would be to start an agent with memory turned on and make sure `memory_search` works. Then, while the same agent run is still active, turn memory off. After that, try using `memory_search` or `memory_get` again. On the fixed version, the tool should be blocked. The test should also make sure the memory tools still work normally when memory is turned on. Prompt injection is not required for this vulnerability. The main problem is a mistake in how permissions are handled. Prompt injection could help an attacker by convincing the agent to use the memory tools at the wrong time, but the bug can still exist without any prompt injection. So prompt injection is only a possible way to trigger the problem, not the actual cause.

Reflection

Working on homework assignment and its tasks helped me understand how AI agents can become a security risk when they are allowed to use tools, read webpages, and interact with the operating system. At first, I thought prompt injection was mostly about tricking a model into saying something it should not say. After completing the direct and indirect injection trials, I understood that the bigger problem is that an agent can sometimes turn text into real actions. One of the most useful parts of the assignment was comparing the direct trial with the indirect trial. In the direct trial, I intentionally told the agent to use the safe-marker skill, so the instruction clearly came from me. In the indirect trial, I only asked the agent to summarize a webpage, but the webpage contained its own instructions. This showed how important it is for an agent to know the difference between trusted user instructions and untrusted external data. I also had several small failures while setting up the lab. I had trouble getting OpenClaw running again after stepping away from the VM, and I had to remember how to return to the correct directory and restart the environment. I also had to fix command syntax mistakes and understand why certain shell commands did not work. Understanding the core conceptions of the different kinds of injections and how to implement it within the assignment. The threat-modeling part made the security ideas much clearer. Drawing the data flow forced me to think about where trust changes between the webpage, the agent, the tool decision, the shell, and the operating system. The advisory analysis also showed me that not every agent security problem is caused by prompt injection. Some vulnerabilities come from authorization mistakes, stale permissions, or unsafe tool behavior. Overall, I learned that AI agent security depends on multiple layers of protection. The model can be useful, but it should not automatically be trusted to make every sensitive security decision on its own.
